Conclusion

A fully
incremental
& fast index

Problem Definition & Existing Methods

Range-Filtering ANNS

Given a query q and range $R = [x, y]$, find top- k vectors with attribute falls in $[x, y]$

Pre-filtering: Linear scan of in-range vectors — too slow

Post-filtering: Standard ANNS + filter out-of-range — may miss k results

Graph-based RFANNS in-filtering indices are superior in query efficiency

Key Challenges

Two open issues in existing RFANNS indices

Challenge 1: Incremental Construction

Most indices are static — require full rebuild on data update

Challenge 2: Selectivity & Correlation

Performance degrades under high selectivity or weak attribute-vector correlation

WoW: First fully incremental graph-based RFANNS index — handles arbitrary ranges with selectivity-aware optimization, achieving oracle-level query efficiency.

Static + Fast Build

WST / HSIG / SeRF

Build-efficient

but query-limited

Static + Fast Query

iRangeGraph / WST

Query-efficient

but no insertion

Limited Incremental

DIGRA / RangePQ

Partial insertion

accuracy degrades

Graph+Tree Structure

Hierarchical window graphs + weighted balanced tree (WBT)

Window Graph = RNG over vectors whose attribute rank is within a window of size $2w$

Ordered attribute array
1 3 4 5 7 11 14 15 16

Object	2D vector	Attribute
v_1	[0.00, 1.73]	1
v_3	[4.25, 0.68]	3
v_4	[0.15, 0.70]	4
v_5	[1.32, 0.11]	5
v_7	[2.62, 0.00]	7
v_{11}	[1.85, 0.97]	11
v_{14}	[3.32, 1.03]	14
v_{15}	[1.79, 2.05]	15
v_{16}	[3.52, 1.92]	16

Query range [5, 15]

(a) An oracle proximity graph

(b) A size-4 window graph

--- Missing edge in window graph → Common edge in both graphs

Size-4 window Graph

Larger layers capture global connectivity;
Small layers give local range precision

Weighted Balanced Tree Hierarchical Window Graphs

Calculate W^2

$W^2_{74} = [10, 99]$

Layer $l = 2, |W^2_a| = 4^2 \times 2$

Layer 2 neighbors W^2

10	72	74	99	[10, 99]
12	29	60	81	[10, 99]
...	...	...	...	...
74	10	35	46	[10, 99]
81	12	51		[10, 99]
98	46	51	60	[10, 99]
99	10	46	48	[10, 99]

Calculate W^1

$W^1_{74} = [48, 99]$

Layer $l = 1, |W^1_a| = 4^1 \times 2$

Layer 1 neighbors W^1

10	35	46	[10, 46]	
12	29	46	[10, 48]	
...	...	...	...	
74	60	72	99	[48, 99]
81	51	72		[51, 99]
98	60	99		[60, 99]
99	72	74		[72, 99]

Calculate W^0

$W^0_{74} = [72, 81]$

Layer $l = 0, |W^0_a| = 4^0 \times 2$

Layer 0 neighbors W^0

10	12	[10, 12]	
12	10	29	[10, 29]
...	...	...	...
74	72	81	[72, 81]
81	74	98	[74, 98]
98	81	99	[81, 99]
99	98		[98, 99]

Index structure

Top-Down Insertion

Insert new vector-attribute pair from top to bottom

- Compute window (via WBT), pick a random entry point inside it.
- Candidates: reuse in-window ones from previous layer if enough, else beam search
- Select $\frac{m}{2}$ nearest neighbors via WindowPrune & RNGPrune

$O(\log^2 n)$ **worst case insertion time, highly parallelizable**

(a) Windows calculation: $\{W_a^0, W_a^1, \dots, W_a^{top}\}$

(b) Candidate acquisition: $\{U^0, U^1, \dots, U^{top}\}$

(c) Two-stage pruning and neighbor connection for all layers

Multi-Layer Candidate Acquisition

Multi-Layer Candidate Acquisition

Beam search traversal within a specified layer range

Inputs: entry ep , query q , range R , layer range $[l_{\max}, l_{\min}]$, beam width ω

Greedy pick nearest vertex; collect in-range candidates per layer

Continue to lower layer when current layer exhausted

Early-stop

Skip lower layers as early as possible

In-range $\rightarrow$ continue

Out-of-range $\rightarrow$ drop

All in $\rightarrow$ stop

Insertion (Alg. 1, Slide 5): searches within windows for neighbor candidates

Query (Alg. 3, Slide 7): called with selectivity-optimized range $[0, l_d]$

Selectivity-Aware Query Processing

Selectivity-Aware Query

A selectivity-optimized two-step query

Problem: Default $[0, top]$ — high layers waste filter checks

n' = in-range count via WBT ($O(\log n)$)

$l_h = \left\lfloor \log_2 \left(\frac{n'}{2} \right) \right\rfloor \rightarrow l_d \in \{l_h, l_h + 1\}$
(best window fit)

l_d window $\approx n' \rightarrow$ most in-range $\rightarrow$ minimal waste

Layer Choice by Selectivity

Range $R = [x, y]$ 

l_x (window $\gg n'$) — Too High

Most out-of-range; heavy waste

l_d (window $\approx n'$) — Optimal

Most in-range; minimal waste $\leftarrow$ Landing

l_0 (fine-grain) — Covered

Fine-grained acquisition with range filter

Step 1: choose landing layer l_d from in-range neighbors n'

Step 2: invoke Alg. 2 (Slide 6) with range $[0, l_d] \rightarrow O(\log n')$, robust across all selectivities

Index Construction: Fast Build, Small Size

Index Size (MB)

Index	Sift	Gist	ArXiv	Wikidata4M	Deep10M

WoW (1 thd.)	765	2,713	3,728	10,371	19,013
WoW (16 thd.)	152	391	623	1,557	3,360

4.9× Faster

BUILD SPEED

- vs DIGRA , most query-efficient static index
- 2nd fastest; #1 on hard datasets

0.4–0.5× Smaller

SIZE

- vs state-of-the-art RFANNS indices
- ≈ #layers × HNSW-L0 size

5.0–6.9× Speedup

SCALABILITY

- Fine-grained vertex-level locks
- Multi-threaded (16 threads)

O(log² n)

GUARANTEE

- Worst-case insertion time
- Fully incremental — no presorting, no rebuild

RFANNS Query: Fast Speed, High Accuracy

4x Faster

QUERY SPEED

- vs UNIFY (HSIG), **best incremental index** across all workloads and all five datasets

1.5x Faster

HIGH SELECTIVITY

- vs best **statically-built** index (DIGRA)
- equals/beats static indices on other selectivity

Steady Performance

Oracle-Level

- DC-Recall curves coincide with oracle HNSW
- $O(\log n')$ complexity, equal to oracle RNG

GRAPH QUALITY

All-Corner Robust

- Steady across difference query correlations
- The ONLY index to be built for 100M scale

SCALABILITY

Dataset	Index Size (MB)	Indexing Time (s)	QPS @90%	QPS @95%	QPS @99%
Wikidata4M	3,112	1,557	2,518	1,486	523
Wikidata41M	37,666	32,183	1,212	713	197
Deep10M	8,430	3,360	6,952	4,521	1,455
Deep100M	90,789	146,465	2,078	1,264	293

iRangeGraph & DIGRA cannot build on Deep100M (OOM). WoW scales further.

Conclusion & Future

What We Achieved

Fully incremental graph-based
RFANNS index

No data presorting or partial indexing

$O(\log^2 n)$ parallel insertion time

Proven $O(\log n')$ query complexity

Key Performance Results

Build: $4.9\times$ faster, $0.4\text{--}0.5\times$ smaller

Query: $4\times$ faster than best incremental

High selectivity: $1.5\times$ faster than static
indices

Matches oracle-level graph efficiency

Future Work

Multi-attribute/spatiotemporal range filtering --- 1D window to high-dimensional rectangles

In-place update and deletion --- repair broken neighborhood in attribute-vector space

Billion-scale dataset extension --- disk-based extension

Thank You
